# Truss Deflections by Electronic Computation of The Williot-Mohr Diagram 

ZA LEE MOH, Structural Designer, and CHARLES E. COOPER, Junior Engineer, State Hıghway Department of Indıana, Indianapolis

#### Abstract

This paper describes the method and procedure used in a digital computer program to find horizontal and vertical movements of all joints of a truss, given the member stresses and the structure properties. The method presented is a solution by analytic geometry of the well-known graphical method of Williot and Mohr. The discussion of the basic program procedure is accompanied by a simplified flow chart. A sample case is included to illustrate the speed, accuracy, and flexibility of the program.

THE ADVANTAGES of truss construction are well known, as witnessed by its widespread use in bridge building. A major disadvantage, however, has been that the design calculations are usually very time-consuming, particularly for indeterminate trusses. This disadvantage, however, is becoming less and less significant with the growing use of the digital computer. There have already been several programs developed for stress analysis of determinate and indeterminate trusses. The program described in this paper deals with another important phase-that of deflections. The necessity for truss deflection computations arises both in the design office, as in the determination of secondary stresses, and in the field, as in the erection of continuous trusses by the cantilever method.

Representative of the several procedures for determining truss deflections are the virtual work, the elastic weight, and Williot-Mohr diagram methods. The method of virtual work is perhaps the best and most direct method for computing one component of deflection for one joint, but this process becomes quite lengthy if the true absolute deflections of all joints are needed. The elastic weight method comes a step closer, but even it is limited to only one component for each joint. This method also becomes lengthy if both the horizontal and vertical components are to be computed. The WilliotMohr diagram yields the resultant deflections of all joints by a single solution. As a graphical method, it too has its disadvantages. Although it is theoretically sound, it is by its very nature limited in accuracy, and for very large structures, it becomes particularly troublesome in matters of scaling and orientation on the paper. But these disadvantages are easily overcome by an algebraic procedure that corresponds to the graphical one. The computations involved in the solution by analytic geometry of the Williot-Mohr diagram are quite simple and are highly repetitive in nature, thus making this method well suited to the electronic computer. The analytic solution is both accurate and fast. It is the purpose of this paper to describe an electronic computer program and the method used therein for the computation of truss deflections.

## NOTATION

Specific symbols are defined where they appear in this paper. In general, however, the following rules apply:

1. Superscripts $T, W$, and $M$ refer, respectively, to the truss diagram, the Williot diagram, and the Mohr correction diagram.
2. Subscripts refer to specific points or vectors. $X$ and $Y$ subscripts are used to denote, respectively, $x$ and $y$ components of vectors.
3. Points on the different diagrams are designated by an upper case letter with a superscript. Thus, for example, $A^{W}$ is the point on the Williot diagram that corresponds with point (or joint) $A^{\top}$ of the truss diagram.
4. The relative positions or locations of the various points are defined by $x$ and $y$ coordinates. For example, $\left(X_{A}^{W}, y_{A}^{W}\right)$ are the coordinates of point $A^{W}$ on the Williot diagram.

## THE WILLIOT-MOHR METHOD

Though no attempt is made here to develop or prove the Williot-Mohr method for determining truss deflections, the following graphical procedure is described as a basis for the development of the analytic procedure.

The Willot diagram, which is drawn first, gives the movements of all joints of the truss with respect to one of the joints and a member that enters that joint. If the member that was used as a direction reference actually rotates with the deformation of the truss, the Mohr correction diagram must be added to give the true absolute movements of all the joints. The scaling of the Mohr correction diagram depends on the amount that the original reference member actually rotates, and the positioning of the correction diagram depends on the actual movement of the original reference joint. If a truss joint that is actually fixed against translation is used as the reference point for the Williot diagram, then both the Williot diagram deflection and the Mohr diagram correction for that joint would be zero. A second point on the Williot diagram may be located by using one of the members entering the fixed joint as a direction reference. A vector equal to the deformation of that member is drawn from the reference point in the direction in which the opposite joint of that member moves with respect to the fixed joint. The location of the first two points on the Williot diagram is shown in Figure 1. Point $F^{W}$ on the Williot diagram corresponds to the fixed joint $F^{\top}$ on the truss diagram. The member connecting joints $F^{\top}$ and $H^{\top}$ is used as a direction reference for the
Williot dagram. The vector $\bar{F}^{W} H^{W}$ represents the magnitude and direction of the movement of joint $\mathrm{H}^{\top}$ with respect to joint $F^{\top}$, and thereby the position of point $\mathrm{H}^{\mathrm{W}}$ on the Williot diagram is established. Note that $\overline{\mathrm{F}}^{\mathrm{W}} \mathrm{H}^{\mathrm{W}}$ is drawn parallel to $\bar{F}^{\top} H^{\top}$.

After having established the first two points, the Williot diagram is completed by proceeding from joint to joint in a series of similar steps. In each step two known Williot diagram points and the deformations of two members are used to establish the position of a third Williot diagram point. One such step is shown in Figure 2, which shows a typical triangular truss panel (Fig. 2a) with joints $\mathrm{A}^{\top}, \mathrm{B}^{\top}$, and $\mathrm{C}^{\top}$ and the corresponding portion of the Williot diagram (Fig. 2b). Points $\mathrm{A}^{\mathrm{W}}$ and $\mathrm{B}^{\mathrm{W}}$ are the known Williot diagram points and $\mathrm{CW}^{W}$ is the point to be determined. The location of point $\mathrm{C}^{\mathrm{W}}$ is determined as follows:

1. The intermediate point $W_{A C}$ is established by the vector $A^{W} W_{A C}$ which is

(a) TRUSS DIAGRAM

## (b) WILLIOT-MOHR DIAGRAM

Figure 1. Example truss and Williot-Mohr duagrams.

(a) TRUSS DIAGRAM

(b) WILLIOT DIAGRAM

Figure 2. Typical triangular truss panel with corresponding portion of Williot diagram.
proportional in length to the deformation of member AC and is drawn parallel to that member from $A^{W}$ to $W_{A C}$ in the direction that $C$ moves with respect to $A^{\top}$. The intermediate point $W$ is established in like manner with respect to member BC.
2. Perpendıculars are erected at points $W_{A C}$ and $W_{B C}$ and are extended until they intersect to locate $C^{W}$.

This procedure is repeated until a corresponding Williot diagram point has been established for each joint of the truss.

With the Williot diagram completed, the Mohr correction diagram can be drawn to give the true absolute movements of all the joints. Because the fixed joint of the truss was used as the starting point for the Williot diagram, the correction involves only the rotation of the structure about that joint until the guided joint is brought back into its predetermined path. The Mohr diagram is geometrically similar to the truss configuration, and furthermore, the lines of the Mohr diagram are perpendicular to the corresponding lines of the truss diagram. Referring again to Figure 1, $\mathrm{F}^{\mathrm{M}}$ coincides with $\mathrm{F}^{\mathbf{w}}$ because $F^{\top}$ is actually fixed in position. Another Mohr diagram point, $G^{M}$, is defined by the intersection of a line drawn through $\mathrm{G}^{\mathrm{W}}$ parallel to the direction of movement of the guided joint $\mathrm{G}^{\top}$ and the line drawn through $F^{W}$ perpendicular to the line connecting points $F^{\top}$ and $G^{\top}$. With these two points, $F^{M}$ and $G^{M}$, determined, the rest of the Mohr diagram can be filled in to scale in accordance with the preceding.

## THE ANALYTIC PROCEDURE

## Input Data

The information needed for the construction of the Williot-Mohr diagram consists of an adequate description of the truss configuration and the deformation (shortening or lengthening) of each member. For the computer program the truss is described by means of two tabulations. The first is a tabulation of joints by number giving a pair of of rectangular coordinates for each joint. The second is a tabulation of members giving the joint numbers of the two joints that each member enters. The coordinates axes are positioned on the truss diagram so that the entire truss lies in the first quadrant, thus eliminating negative coordinates.

In addition to the joint and member tabulations, the numbers of the fixed and guided joints and the direction in which the guided joint moves must be indicated. The direction of movement of the guided joint is expressed as an angle, $\beta^{\prime}$, measured from the $X$-axis. Also, because the output deflections (answers) are to be given in $x$ and $y$ components, the desired directions for these components (such as horizontal and vertical) are indicated by an angle, $a$, measured from the respective coordinate axes used to describe the truss. For both $\alpha$ and $\beta^{\prime}$ the usual sign convention applies; i. e., counterclockwise is positive, clockwise is negative. Note that, regarding algebraic sign, these angles are given with respeçt to the original coordinate axes used to describe the truss configuration.

The data needed for computing the member deformations include the axial force, cross-sectional area, and length of each member along with the modulus of elasticity of the truss material. The axial forces (stresses), S , and the cross-sectional areas, $A$, are included in the member table, and the lengths are determined from the joint coordinates. The appropriate conversion factors may be incorporated into the figure for modulus of elasticity in order that all other data may be entered "as found" without regard to units. Based on the data thus provided, the computations for truss deflections can be started.

## Preliminary Computations

The guiding principle in the preparation of the format for input data was that these data should be limited as nearly as possible to those quantities that are readily available, leaving conversions and other preliminary computations to the computer program. The first of these prelıminary computations to be considered here is that for member deformations. Because the subsequent computations will involve only $x$ and $y$ components, the unit deformation rather than the total deformation is computed for each member at this time. Unit deformation, $\delta$, nay be defined as the amount by which a unit length of a member elongates or shortens. In accordance with the definition of modulus of elasticity,

$$
\begin{equation*}
\delta=\frac{S}{A E} \tag{1}
\end{equation*}
$$

The algebraic sign, of course, depends on the sign of $S$, which is considered positive for tension and negative for compression.

Having oriented the original coordinate axes on the basis of conveniencefor describing the truss configuration, the next step is to transform the coordinates so that

(a) the origin coincides with the fixed joint and (b) the $X$ and $Y$ axes lie, respectively, in the directions in which the final deflection components are desired; e.g., horizontal and vertical. The formulas for transformation of coordinates are

$$
\begin{align*}
& x=\left(y^{L}-k\right) \sin a+\left(x^{\prime}-h\right) \cos a  \tag{2a}\\
& y=\left(y^{\prime}-k\right) \cos a-\left(x^{\prime}-h\right) \sin a \tag{2b}
\end{align*}
$$

in which $x$ and $y$ are the coordinates of a point in the new system, $x^{\prime}$ and $y^{1}$ are the coordinates of the same point in the old system, $h$ and $k$ are the coordinates of the origin of the new system in terms of the old system, and $a$ is the angle that the new axes makes with the corresponding old axes.

Figure 3a shows a sample truss diagram with angles $a$ and $\beta^{\prime}$ labeled and the original coordinate axes used to describe the truss. Figure 3b shows the positioning of the new axes, presuming that in this case horizontal and vertical components of joint deflections are desired. Note that the angle $\beta$ is found as follows:

$$
\begin{equation*}
\beta=\beta^{\prime}-\alpha \tag{2c}
\end{equation*}
$$

## The Analytic Solution

Once the unit deformations have been
Figure 3. Orientation of coordinate axes.
oriented as indicated above, the rest of the procedure involves only x and y components. As in the graphical solution, the first two points to be located on the Willot diagram are those corresponding with the fixed joint and the opposite joint of a member that enters the fixed joint. The Wilhot diagram coordinates ( $x_{F}^{W}, y_{F}^{W}$ ) of the point, $F^{W}$, which corresponds with the fixed joint, $F^{\top}$, are both equal to zero (see Fig. 1). If the member, $F H$, which connects joints $F^{\top}$ and $H^{\top}$, is used as the direction reference for the Williot diagram, then the Williot diagram coordinates for point $H^{\mathbf{W}}$ are computed by resolving the movement of joint $H^{\top}$ with respect to joint $F^{\top}$ into $x$ and $y$ components. Thus:

$$
\begin{aligned}
& x_{H}^{W}=\left(x_{H}^{\top}-x_{F}^{\top}\right) \delta_{F H} \\
& y_{H}^{W}=\left(y_{H}^{\top}-y_{F}^{\top}\right) \delta_{F H}
\end{aligned}
$$

in which $\delta_{\mathrm{FH}}$ is the unit deformation for the member FH. But because the truss diagram coordinates for the fixed joint are zero, the equations become

$$
\begin{align*}
& x_{H}^{W}=x_{H}^{\top} \delta_{F H}  \tag{3a}\\
& y_{H}^{W}=y_{H}^{\top} \delta_{F H} \tag{3b}
\end{align*}
$$

The remaining step-by-step procedure for completing the table of Williot diagram coordinates is again analogous to that of the graphical procedure. However, instead of using the length of a member to compute its deformation, the $x$ and $y$ components of the vector representing the distance from the near end of the member to the far end must be used in order to account for the direction in which the far end moves with respect to the near end. If joints $A^{\top}$ and $B^{\top}$ are at the "near ends" of members $A C$ and BC , respectively, and if the "far ends" of both members enter joint $\mathrm{C}^{\top}$ (see Fig. 2a), then the length vectors are computed as follows:

$$
\begin{align*}
& L_{X A}=x_{C}^{\top}-x_{A}^{\top}  \tag{4a}\\
& L_{Y A}=y_{C}^{\top}-y_{A}^{\top}  \tag{4b}\\
& L_{X B}=x_{C}^{\top}-x_{B}^{\top}  \tag{4c}\\
& L_{Y B}=y_{C}^{\top}-y_{B}^{\top} \tag{4d}
\end{align*}
$$

in which $L_{X A}$ is the $x$ component of the vector $A^{\top} C^{\top}, L_{Y A}$ is the $y$ component of the same vector, etc. For the typical triangular truss panel of Figure 2, the Williot diagram coordinates of points $A^{W}$ and $B^{W}$ are known and the coordinates of point $C^{W}$ are to be computed. The inter medrate points $W_{A C}$ and $W_{B C}$ are obtained by adding the respective vectors representing the movement of joint $C^{\top}$ with respect to joint $A^{\top}$ parallel to member $A C$ and the movement of joint $C^{\top}$ with respect to joint $B^{\top}$ parallel to member $B C$ to the points $A^{W}$ and $B^{W}$. Therefore, the coordinates of these intermediate points may be computed by using the following equations:

$$
\begin{align*}
& x_{A C}=L_{X A} \delta_{A C}-x_{A}^{W}  \tag{5a}\\
& y_{A C}=L_{Y A} \delta_{A C}-y_{A}^{W}  \tag{5b}\\
& x_{B C}=L_{X B} \delta_{B C}-x_{B}^{W}  \tag{5c}\\
& y_{B C}=L_{Y B} \delta_{B C}-y_{B}^{W} \tag{5d}
\end{align*}
$$

Finally, the location of point $\mathrm{C}^{\mathrm{W}}$ is defined by the intersection of the lines perpendicular to the vectors $A W_{A C}$ and $B W_{B C}$ and passing through points $W_{A C}$ and $W_{B C}$, respectively. The general equation of a line given a point $\left(x_{1}, y_{1}\right.$ ) on that line and the slope, $m$, of a line normal to it is

$$
y=y_{1}-\frac{1}{m}\left(x-x_{1}\right)
$$

The slopes of vectors $\overline{A^{W} W_{A C}}$ and $\overline{B^{W} W_{B C}}$ are equal to $\frac{L_{Y A}}{L_{X A}}$ and $\frac{L_{Y B}}{L_{X B}}$, respectively. $B y$ substituting these slopes and the coordinaces of the corresponding points $W_{A C}$ and $W_{B C}$ into the general equation above, the following equations for the lines $\overline{W_{A C} C^{W}}$ and $\overline{W_{B C} C^{W}}$ result:

$$
\begin{aligned}
& y=y_{A C}-\frac{L_{X A}}{L_{Y A}}\left(x-x_{A C}\right) \\
& y=y_{B C}-\frac{L_{X B}}{L_{Y B}}\left(x-x_{B C}\right)
\end{aligned}
$$

Solving these two equations simultaneously for the coordinates, $\left(x_{c}^{w}, y_{c}^{w}\right)$, of point $C^{w}$ yields

$$
\begin{align*}
& x_{C}^{w}= \frac{\frac{x_{A C} L_{X A}}{L_{Y A}}-\frac{x_{B C} L_{X B}}{L_{Y B}}+y_{A C}-y_{B C}}{\frac{L_{X A}}{L_{Y A}}-\frac{L_{X B}}{L_{Y B}}}  \tag{6a}\\
& y_{C}^{w}= \frac{y_{A C} L_{Y A}}{L_{X A}}-\frac{y_{P C} L_{Y B}}{L_{X B}}+x_{A C}-x_{B C}  \tag{6b}\\
& \frac{L_{Y A}}{L_{X A}}-\frac{L_{Y B}}{L_{X B}}
\end{align*}
$$

Therefore, Eqs. 4-6 may be used to locate each successive Williot diagram point with respect to the coordinate axes after the two starting points have been located, the first being at the origin and the second by Eqs. 3a and 3b. Special consideration must be given, however, if the result of any one of the Eqs. 4a-4d is zero, as would be the case for a member parallel to either coordinate axis. The following rules apply:

$$
\begin{align*}
& \text { If } L_{X A}=0 \text {; then } y_{C}=y_{A C}  \tag{7a}\\
& \text { If } L_{Y A}=0 \text {; then } x_{C}=x_{A C}  \tag{7b}\\
& \text { If } L_{X B}=0 \text {; then } y_{C}=y_{B C}  \tag{7c}\\
& \text { If } L_{Y B}=0 \text {; then } x_{C}=x_{B C} \tag{7d}
\end{align*}
$$

Having completed the Williot diagram as indicated above, the next step is to compute the angle, $\theta$, through which the truss must be rotated about its fixed joint to bring the guided joint back into its previously designated path. Because $\theta$ is quite small in any practical case, it may be taken as equal to its tangent, thus:

$$
\begin{equation*}
\theta=\frac{y_{G}^{w}-x_{G}^{w} \tan \beta}{x_{G}^{T}} \tag{8}
\end{equation*}
$$

in which $x_{G}^{\top}$ is the $x$ coordinate of the guided joint (truss diagram) and $\left(x_{G}^{W}, y_{G}^{W}\right)$ are the coordinates of the corresponding Williot diagram point. The coordinates for each point on the Mohr correction diagram (see Fig. 1b) may be computed by the following equations:

$$
\begin{aligned}
& x_{N}^{M}=-\theta y_{N}^{\top} \\
& y_{N}^{M}=\theta x_{N}^{\top}
\end{aligned}
$$

in which $x_{N}^{\top}$ and $y_{N}^{\top}$ arethe coordinates of any joint, $N^{\top}$, of the truss diagram and $x_{N}^{M}$ and $y_{N}^{M}$ are the coordinates of the corresponding Mohr correction diagram point. The $x$ and $y$ components of the true absolute movement of each truss joint may be obtained by subtracting, respectively, the coordinates of the Mohr diagram points from the coordinates of the corresponding Williot diagram points; thus:

$$
\begin{align*}
& D_{X N}=x_{N}^{W}+\theta y_{N}^{\top}  \tag{9a}\\
& D_{Y N}=y_{N}^{W}-\theta x_{N}^{\top} \tag{9b}
\end{align*}
$$

in which $D_{X N}$ and $D_{Y N}$ are the $x$ and $y$ components of the deflection of any joint, $N^{\top}$, respectively.

## THE COMPUTER PROGRAM

A computer program for the computation of truss deflections based on the described method was written for the IBM 650 data processing system. This program follows basically the procedure set forth in the simplified flow chart, Figure 4. The program was limited arbitrarily to trusses with up to 99 non-redundant members. It is, of course, also limited to those truss deflection problems that can be solved by the WilliotMohr method.

Figure 4. Simplified flow chart for computer program.

Input data include the joint and member tabulations; the modulus of elasticity, and the respective numbers of the fixed and guided joints, as previously indicated. In addition to these, the joint and member counts are required. The output consists of the $x$ and $y$ components of deflection for each joint.

Running time varies from about 4 to 12 sec per joint depending on the order in which the truss members are numbered. If the members are numbered in the order in which they would be used in the construction of the Williot diagram, the searching time for the machine is greatly reduced. Regardless of member numbering, however, the total running time for a 99 -member truss would not exceed about 10 min .

## SAMPLE CASE

The New Albany-Louisville Bridge on Interstate 64 over the Ohio River was used to illustrate the described truss deflection program. The bridge is a double-decked, tiedarch truss 797.5 ft long from fixed joint to guided joint. Bridge elevations and joint coordinates are shown in Figure 5. Physical properties and dead-load stresses are listed in Table 1. Using for the modulus of elasticity of the truss material $29,000 \mathrm{ksi}$, the horizontal and vertical components of deflection (Table 2) were computed for each joint in a total of 3 min 5 sec , including read-in and punch-out time, by the IBM 650 digital computer.

## NEW ALBANY-LOUISVILLE BRIDGE

Figure 5. Sample case (New Albany-Louisville Bridge).

## REMARKS

The method just described for the analysis of truss deflection is nothing new. It is only an analytic version of the commonly used Williot-Mohr diagram. The procedure is also similar in many respects to K. H. Chu's method (1), which was developed for use with a desk calculator. The sign convention is always troublesome in the WilliotMohr graphical method, but it is taken care of automatically by the computer program. Length of each member is determined from the joint coordinates, a fact that also simplifies the input data.

## ACKNOWLEDGMENT

The authors wish to express their sincere thanks to C. R. Ruminer and M. G. Dukes, both of the State Highway Department of Indiana, for their encouragement and guidance.
