## Defining

Exploratory
Modeling and
Analysis (EMA)

EMA is a systematic approach to perform sensitivity analysis using models when many of the model inputs cannot be asserted with confidence, so that a wide range of different input assumptions can be tested simultaneously, looking for patterns in the results to guide robust decision-making (RDM).

## CV/AV Application: <br> Develop an Approach for Modeling the System

## Adapted Existing Models for the Jacksonville, Florida Region:

- DaySim activity-based travel demand simulation
- TransModeler dynamic traffic simulation
- Feedback between the simulation models

## Assumptions

- Detailed simulation models will facilitate a realistic representation of new aspects of AV/CV demand and supply for exploratory analysis.
- Relevant findings from these detailed models can be adapted for use with simpler
 (trip-based and static) models.

## DaySim: Activity-based model

- Simulates a day's travel tours and activities for each person in a synthetic population
- Schedules travel and activities to be non-overlapping
- Operates at the parcel level of spatial detail
- Already implemented in the NERPM model used by NFTPO

## Enhancements Made for this Project (and Applied Elsewhere)

- Auto ownership model includes choice between conventional and autonomous private vehicles
- The "paid rideshare" (TNC) mode added to mode choice
- TNCs can be specified to use AVs
- AV passengers can have lower disutility of travel time
- Can use separate auto skim matrices for AVs

## TransModeler: Microscopic DTA

## Microscopic in Level of Detail

- Referenced to ground truth with accurate geometry
- Lane level and intersection area representation
- Temporal dynamics (as low as 0.1-sec)
- 2-d and 3-d dynamic visualization

## Microscopic in Modeling Accuracy

- Microscopic (car following, lane changing)
- Employs realistic route choice models
- Handles complex network infrastructure (signals, variable message signs, sensors, etc.)
- Simulates multiple modes, user classes, vehicle types

## Implementation: Jacksonville, FL

## Implementation: Jacksonville, FL

## Implementation: Jacksonville, FL

## Information Flows at Model Interfaces

## DaySim to TransModeler >>>>

A trip list (over 6 million daily trips), parcel-to-parcel, minute-to-minute.
Trip matrices for freight, externals, etc. Processed into compatible trip lists with more detailed times and locations.

## TransModeler to DaySim >>>>

Dynamic travel time skims, TAZ-TAZ, 30 minute periods, by user class (SOV, HOV, Conventional vehicles, Autonomous vehicles)

## Performing the ABM + DTA Runs

- Windows machines with 12 cores
- TransModeler DTA - 5 to 9 AM, 25 iterations $\rightarrow 24$ hours
- DaySim ABM $\rightarrow 45$ min
- DaySim using AM dynamic skims + transpose for PM peak and static assignment for midday and night periods
- Ran 3 to 5 feedback loops
- Transit skims held constant
- Runtimes limited the number of EMA runs that could be done

## Experimental Design for 16 Scenario Runs (Plus Base Scenario)

## Possible Extensions to the Work

- Run for a wider range of assumptions and scenarios, using regression approach to summarize
- Differences in Value of Time
- Remote parking locations for private Avs
- Cost structures and levels for TNC's
- Occupancy (pooling) assumptions for "shared" (TNC) AVs
- Changes in household activity patterns to use AVs as "private taxis"
- Lower priority for zero-occupant AVs (ZOVs) on the network
- Additional types of network scenarios (e.g., AV-based TNCs can use HOV lanes)
- See if the network behavior simulated in the DTA can be replicated with static assignment methods
- Would allow many more exploratory runs to be done quickly

How-To: Model Impacts of Connected and Autonomous/Automated Vehicles (CAVs) and RideHailing with an Activity-Based Model (ABM) and Dynamic Traffic Assignment (DTA)-An Experiment

U.S. Department of Transportation Federal Highway Administration

## Questions

## Verification of Dynamic Skims

Dynamic versus static

Static Skims (SOV)
